

Commodity Trading Option Pricing

28.3.2011

Optionpricing

- Relative Pricing → Comparativeness
- Accessible through probabilistic approach → Which is the right probability distribution?
- Accessible through “arbitrage free” approach → Practicability?

Plain Vanilla Option

- A Call is the right to BUY the underlying instrument at the expiration date at the STRIKE price. The value at expiration is the greater of (price of the underlying the that date minus strike price) and zero
- A Put is the right to SELL the underlying instrument at the expiration date at the STRIKE price. The value at expiration is the greater of (strike price minus price of the underlying the that date) and zero

— Wert Call bei Ausübung

— Wert Put bei Ausübung

Probabilistic Approach

- What is the value of call strike 3 on a dice, one roll?

➔ Know Probability Distribution!

Probabilistic Approach

- Sum of all payout multiplied by there probability over all events:

$$0 * 1/6 + 0 * 1/6 + 0 * 1/6 + 1 * 1/6 + 2 * 1/6 + 3 * 1/6$$

Arbitrage Free Approach

- Situation A: An Asset will be worth either 20% more or 10% less, tomorrow
- Situation B: An Asset will be worth either 10% more or 40% less, tomorrow
- Which Call at-the-money (Strike today's price) is more valuable?
- Idea from Didier Cossin, IMD

Pricing the Calls

- Assumption: one can buy or sell both underlyings and call freely and without fees or interest rate (the later make no substantial difference). Assume Price underlying 100.
- Suppose the price at the current market is very low, buy 1000 calls and sell $\Delta * 1000$ underlyings, such that in both cases you receive the same profit.
- If you manage to do so, you can make a sure profit as long the price is too low.

Case A

- Price Underlying 100, Price Call C
- Buy 1000 Calls – pay $1000 \cdot C$
- sell $\Delta \cdot 1000$ underlyings – receive $\Delta \cdot 100'000$
- Upper Case Profit = $1000 \cdot (20 - C) - \Delta \cdot 20'000$
- Lower Case Profit = $1000 \cdot (-C) + \Delta \cdot 10'000$

Case B

- Price Underlying 100, Price Call C
- Buy 1000 Calls – pay $1000 * C$
- sell $\Delta * 1000$ underlyings – receive $\Delta * 100'000$
- Upper Case Profit = $1000 * (10 - C) - \Delta * 10'000$
- Lower Case Profit = $1000 * (-C) + \Delta * 40'000$

General Case

- Price Underlying 100 can be either X up ($100+X$) or Y down ($100-Y$), Price Call C
- Buy 1000 Calls – pay $1000 \cdot C$
- sell $\Delta \cdot 1000$ underlyings – receive $\Delta \cdot 100'000$
- Upper Case Profit = $1000 \cdot (X - C) - \Delta \cdot X \cdot 1000$
- Lower Case Profit = $1000 \cdot (-C) + \Delta \cdot Y \cdot 1000$
- Equal if $\Delta = X / (X + Y)$

Discussion (I)

- Option prices Volatility not expectation!

(TAI????)

- Independent of probabilistic view?
Check $X > 0$ and $Y < 0$. →

Case B: The fact that the current price is much closer to the upper case than to the lower case implies that the

Discussion (II)

- Probabilistic View $p :=$ probability that price increases (upper case) / $1-p :=$ probability that price decreases (lower case)
- Case A: $p \cdot 120 + (1-p) \cdot 90 = 100$
→ $p = 1/3$; $1-p = 2/3$
- Case B: $p \cdot 110 + (1-p) \cdot 60 = 100$
→ $p = 4/5$; $1-p = 1/5$

Probability = Model for

- Randomness \Leftrightarrow Uncertainty
- Few things are truly random, lots of influence are not detectable in reasonable time
